Conservation of Isotopic Spin and Isotopic Gauge Invariance*

C. N. YANG † AND R. L. MILLS

Brookhaven National Laboratory, Upton, New York

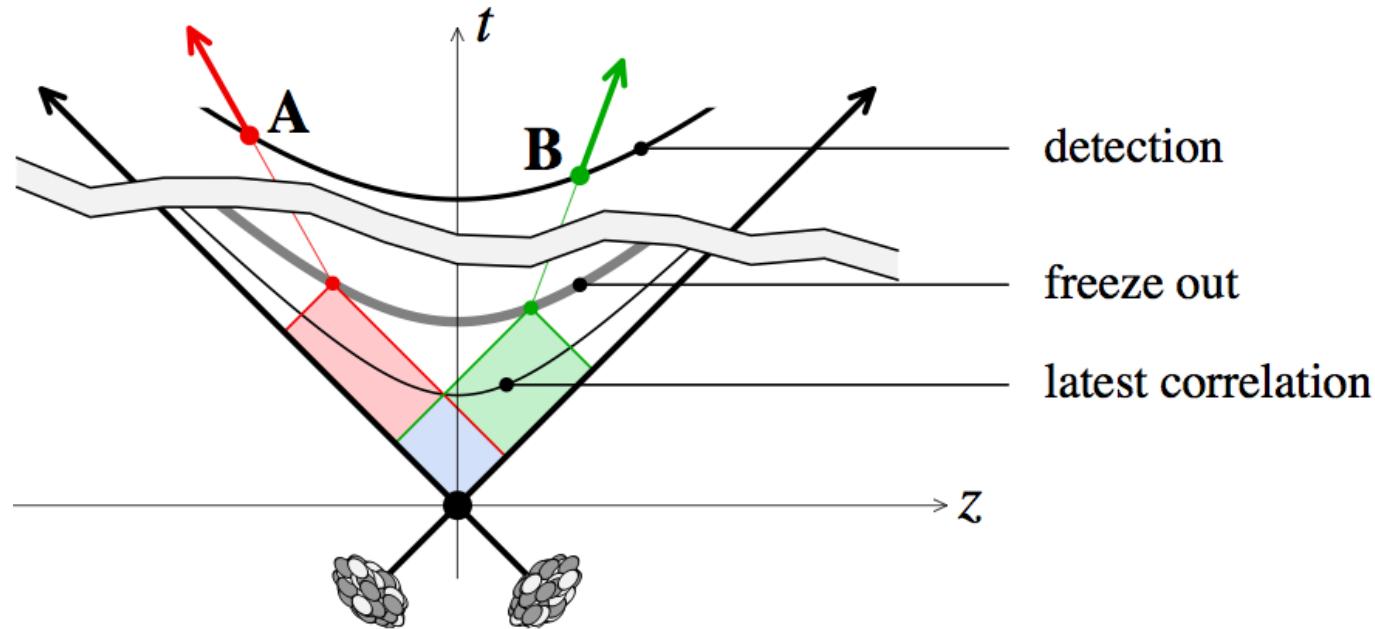

(Received June 28, 1954)

It is pointed out that the usual principle of invariance under isotopic spin rotation is not consistent with the concept of localized fields. The possibility is explored of having invariance under local isotopic spin rotations. This leads to formulating a principle of isotopic gauge invariance and the existence of a **b** field which has the same relation to the isotopic spin that the electromagnetic field has to the electric charge. The **b** field satisfies nonlinear differential equations. The quanta of the **b** field are particles with spin unity, isotopic spin unity, and electric charge $\pm e$ or zero.

Possibly the most important paper from BNL...yet not mentioned in the
APS plaque on BNL's historic achievements ... outside in the Lounge

The J (aka J/ ψ) discovery--November revolution, 1974--didn't make it in either...

Long range rapidity correlations as a chronometer

$$\tau \leq \tau_{\text{frz-out}} \exp \left(-\frac{1}{2} |y_A - y_B| \right)$$

- ❖ Long range correlations sensitive to very early time (fractions of a femtometer $\sim 10^{-24}$ seconds) dynamics in collisions

What's the underlying QCD dynamics?

- ◆ Is it final state collective flow of the world's smallest droplets?
- ◆ Is it the initial state dynamics arising from rare configurations in the hadron wavefunctions?
- ◆ Or, is it some combination, where there is a smooth transition from one description to the other?

Option 1 stretches to the limit -- the applicability of thermodynamic and hydrodynamic concepts in high energy physics

Option 2 stretches to the limit -- our understanding of the quark-gluon sub-structure of hadrons

Sensitive measure of collectivity: azimuthal cumulants

2m-particle azimuthal cumulants

Borghini,Dinh,Ollitrault, nucl-th/0105040

$$c_n \{2m\} = \langle\langle e^{in(\phi_1 + \cdots + \phi_m - \phi_{m+1} - \cdots - \phi_{2m})} \rangle\rangle$$

If cumulants factorize into product of correlations relative to a reaction plane, define flow coefficients:

$$v_n \{2\}^2 \equiv c_n \{2\} \quad v_n \{4\}^4 \equiv -c_n \{4\} \quad v_n \{6\}^6 \equiv c_n \{6\}/4$$

Spatial eccentricities: $\epsilon_n = \frac{1}{\langle r_\perp^n \rangle} \int d^2 r_\perp e^{in\phi_r} r_\perp^n \frac{dN}{dy d^2 r_\perp}$

A number of simple “Gaussian” models give $\epsilon_n \{2\} > \epsilon \{4\} = \epsilon \{6\} = \dots$

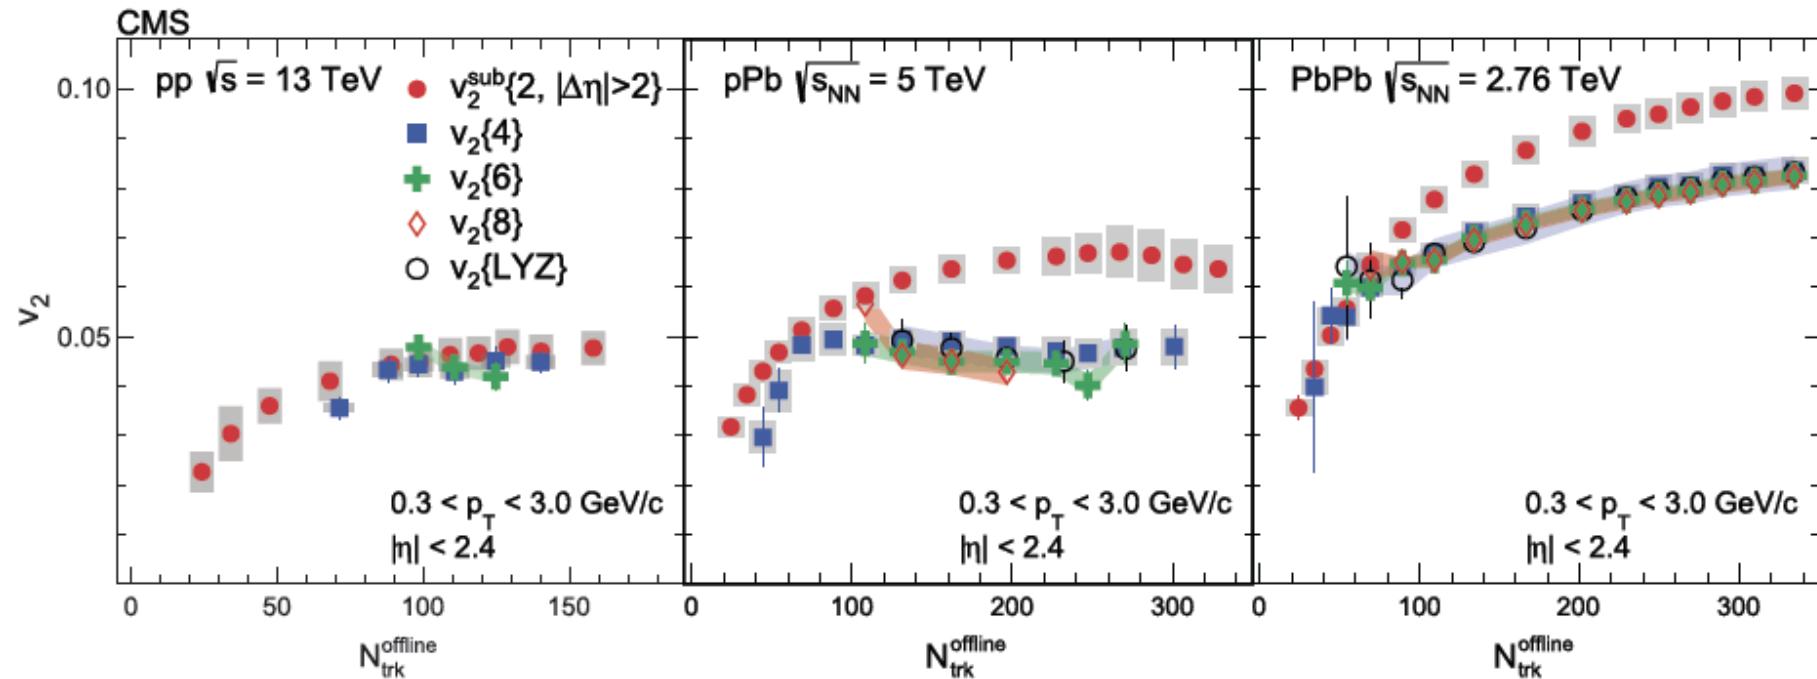

Hydro linear response: $v_n \{m\} \approx c_n \epsilon_n \{m\}$

Collectivity across system size

Collectivity across wide energy scales

Schenke, RV:1407.7557

Panta Rhei?

Heraclitus of Ephesus
535-475 BC

Natural in hydro – yet, very few ab initio hydro computations of 4-particle cumulants for p+A -- none for p+p

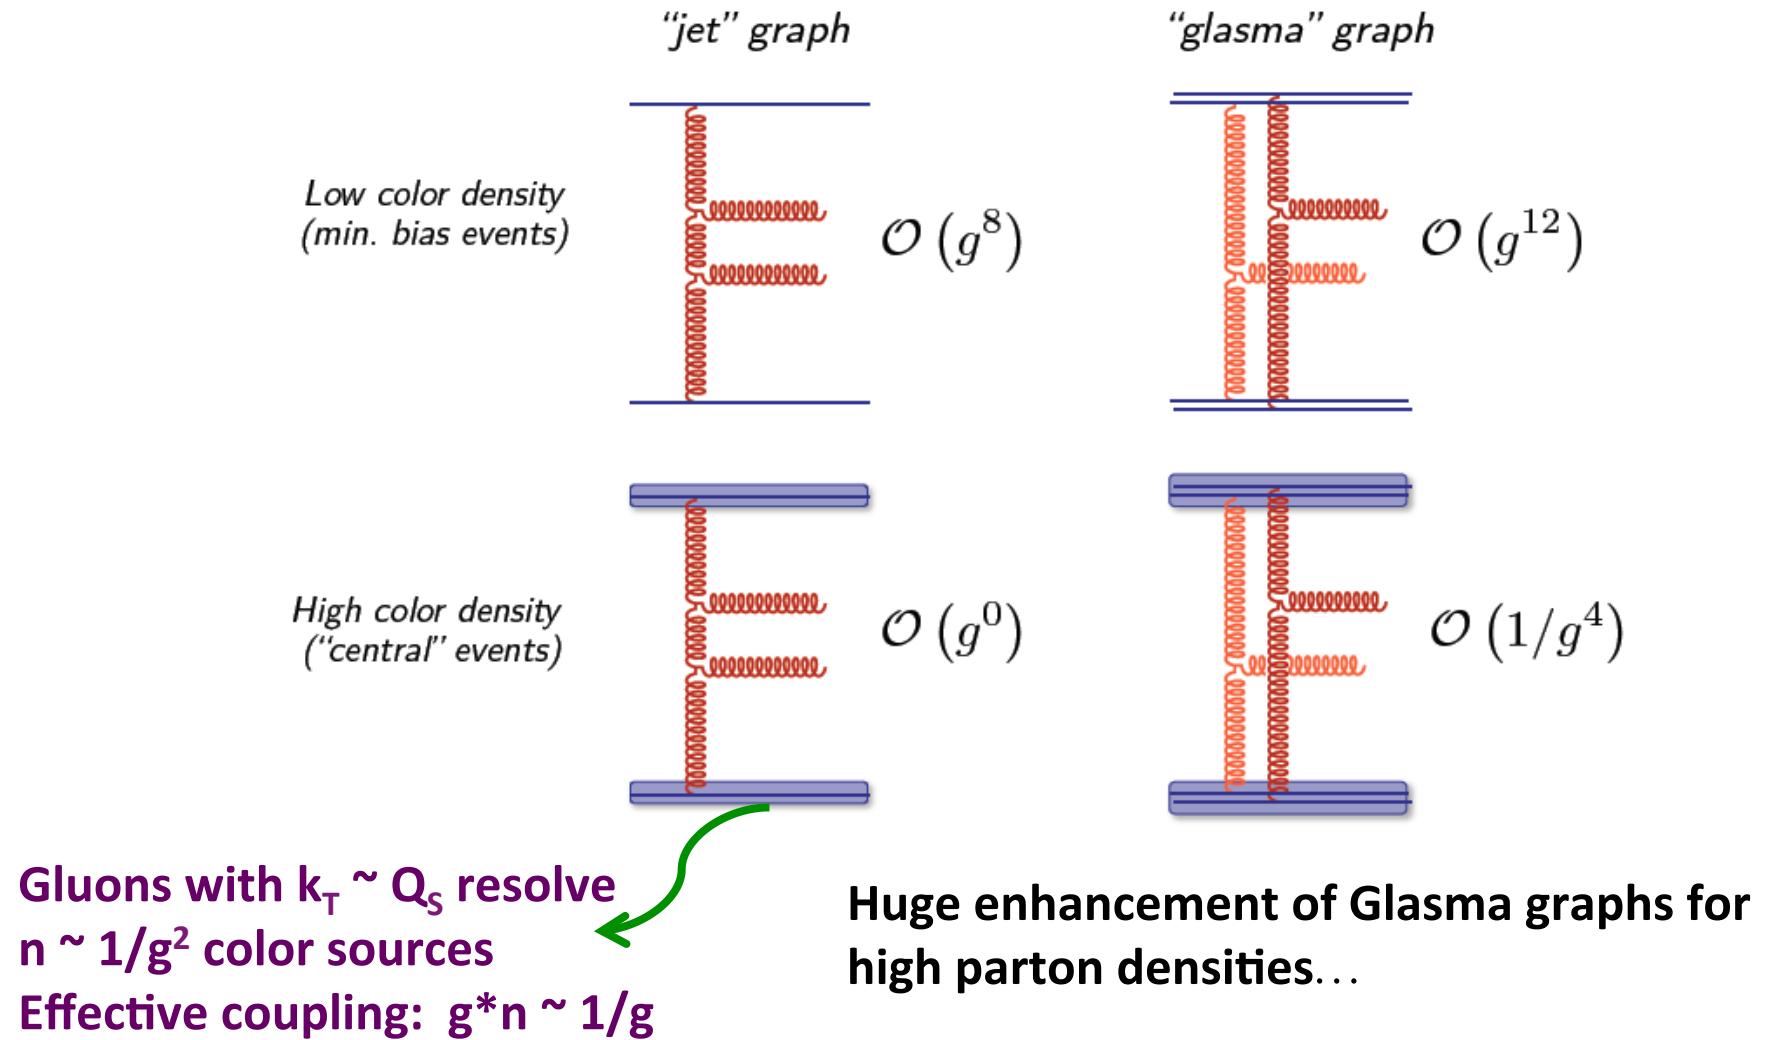

Problems with hydro interpretation for small systems:

- i) Absence of “jet” quenching
- ii) Lack of convergence of hydro expansion (large Knudsen numbers)
- iii) Effects seen for small multiplicity and high p_T (9 GeV)

Can we understand multiparticle correlations in an *ab initio* approach ?

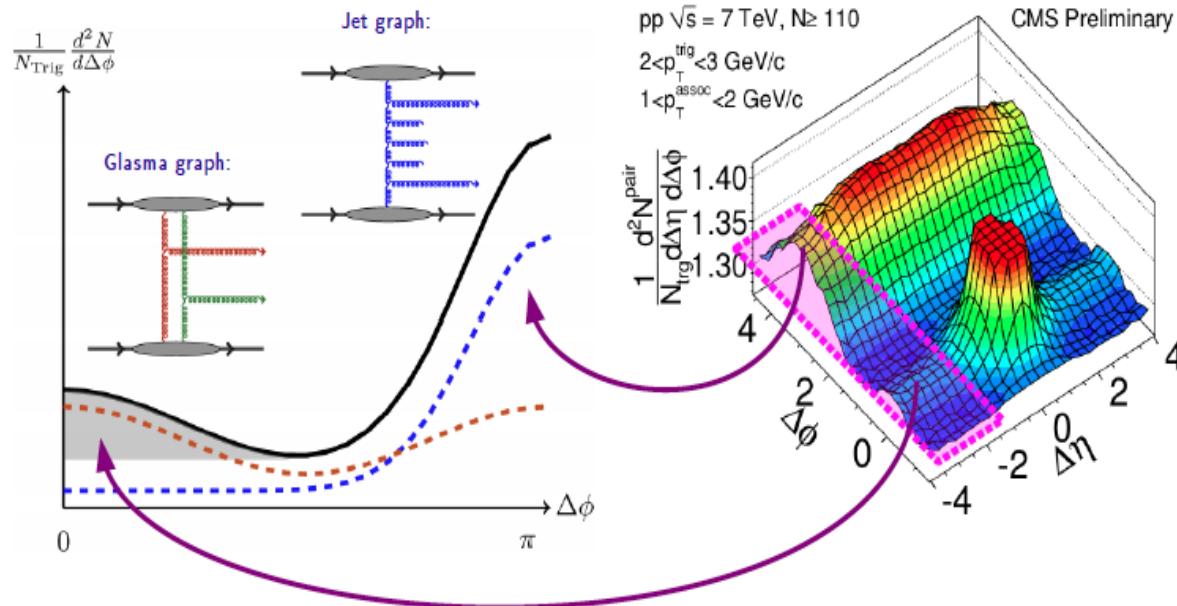

Review: Dusling,Li,Schenke, arXiv:1509.07939

Glasma graph approximation: power counting

Dumitru,Dusling,Gelis,Jalilian-Marian,
Lappi,Venugopalan, PLB697 (2011)21
Dusling,Venugopalan,PRL108 (2012)262001

Anatomy of long range collimations

RG evolution of Glasma graphs:

$$C(\mathbf{p}, \mathbf{q}) \propto \frac{g^4}{\mathbf{p}_\perp^2 \mathbf{q}_\perp^2} \int d^2 \mathbf{k}_{1\perp} \Phi_{A_1}^2(y_p, \mathbf{k}_{1\perp}) \Phi_{A_2}(y_p, \mathbf{p}_\perp - \mathbf{k}_{1\perp}) \Phi_{A_2}(y_q, \mathbf{q}_\perp - \mathbf{k}_{1\perp})$$

+ permutations

RG evolution of the mini-jets: $C_{\text{dijet}}(\mathbf{p}, \mathbf{q}) \propto \Phi_A \otimes \Phi_B \otimes G_{\text{BFKL}}$

Good agreement with data for $\mathbf{p}_T > Q_S$

However no odd harmonics v_3, v_5 for gluons

because $C(\mathbf{p}, \mathbf{q}) = C(\mathbf{p}, -\mathbf{q})$

Dusling, RV, PRD 87, 051502 (R) (2013); PRD87 (2013) 094034
Dusling, Tribedy, RV, PRD93 (2016) 014034

Tracing azimuthal initial state correlations

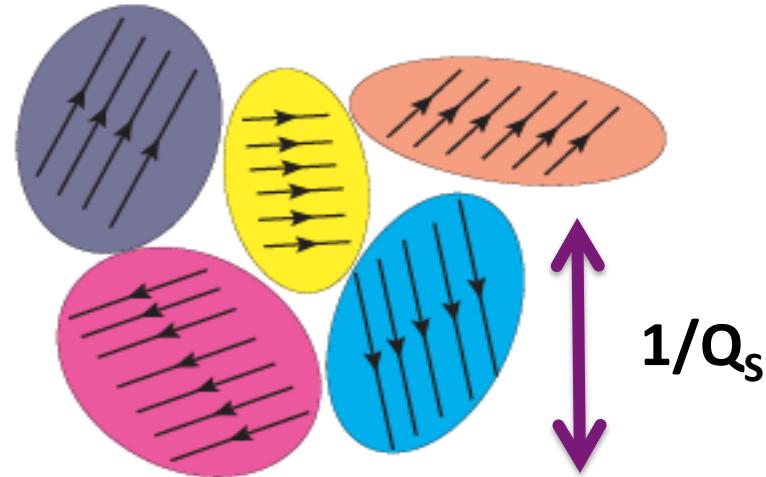

Simple ab initio initial state model:

Multi-particle correlations from Eikonal scattering of partons
off color domains in a nuclear target

Dumitru,Gianini, arXiv:1406.5781

Dumitru,Skokov,arXiv:1411.6630,

Dumitru,McLerran,Skokov,arXiv:1410.4844

Eikonal scattering: the parton model

Color rotation of parton in external field by a lightlike Wilson line

$$W[A](x) = \mathcal{P} \exp \left[ig \int dz^+ A_a^-(z^+, x) \right]$$

Parton distribution after coherent multiple scattering off nucleus:

$$\frac{dN_q}{d^2p} = \frac{1}{\pi^2} \int d^2b \int \frac{d^2k}{(2\pi)^2} \int d^2r e^{-b^2/B} e^{-k^2B} \left\langle D(b + r/2, b - r/2) \right\rangle$$

Wigner function Dipole correlator

$$D(x, \bar{x}) = \frac{1}{N_c} \text{Tr} [W(x) W^\dagger(\bar{x})]$$

B is transverse area of proton

Bjorken, Kogut, Soper, Phys. Rev., D3:1382, (1971)

Dumitru, Jalilian-Marian, Phys. Rev. Lett., 89:022301, (2002)

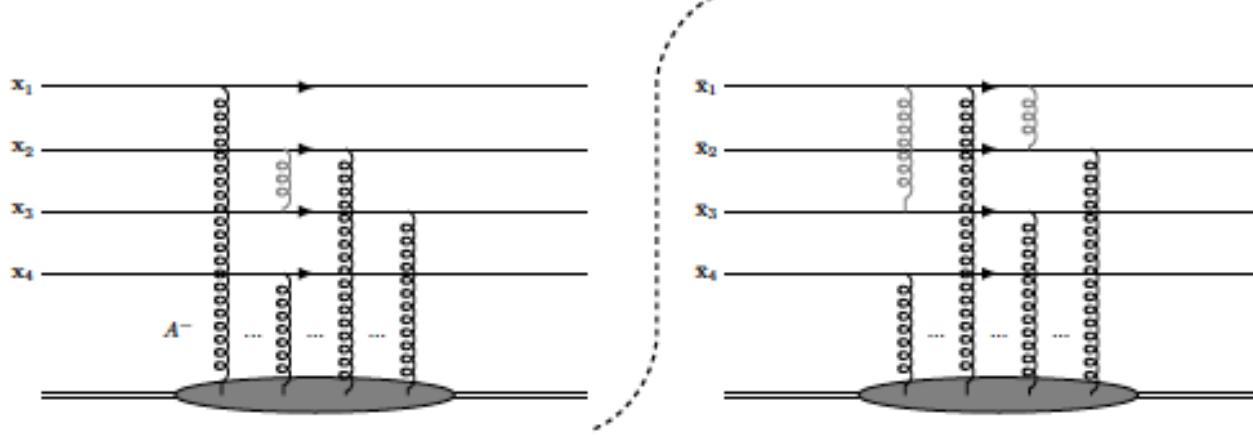

Multiparton Eikonal scattering

Two partons:

$$\frac{d^2 N}{d^2 p_1 d^2 p_2} \simeq \frac{1}{(\pi B_p)^2} \int_{x\bar{x}y\bar{y}} e^{-(x^2 + \bar{x}^2)/2B_p} e^{-(y^2 + \bar{y}^2)/2B_p} e^{ip_1 \cdot (x - \bar{x})} e^{ip_2 \cdot (y - \bar{y})}$$

$$\times \left\langle \frac{1}{N_c} \text{Tr} [W(x) W^\dagger(\bar{x})] \frac{1}{N_c} \text{Tr} [W(y) W^\dagger(\bar{y})] \right\rangle \propto \langle D D \rangle$$

Four parton

$$d^4 N \sim \int \left\langle \text{Tr} [W(w) W^\dagger(\bar{w})] \text{Tr} [W(x) W^\dagger(\bar{x})] \text{Tr} [W(y) W^\dagger(\bar{y})] \text{Tr} [W(z) W^\dagger(\bar{z})] \right\rangle$$

$$\propto \langle D D D D \rangle \text{ and so on ...}$$

Oversimplification: n-particle Wigner distributions factorize

$$W_{q^n}(b_1, k_1, \dots, b_n, k_n) = W_q(b_1, k_1) \cdot \dots \cdot W_q(b_n, k_n)$$

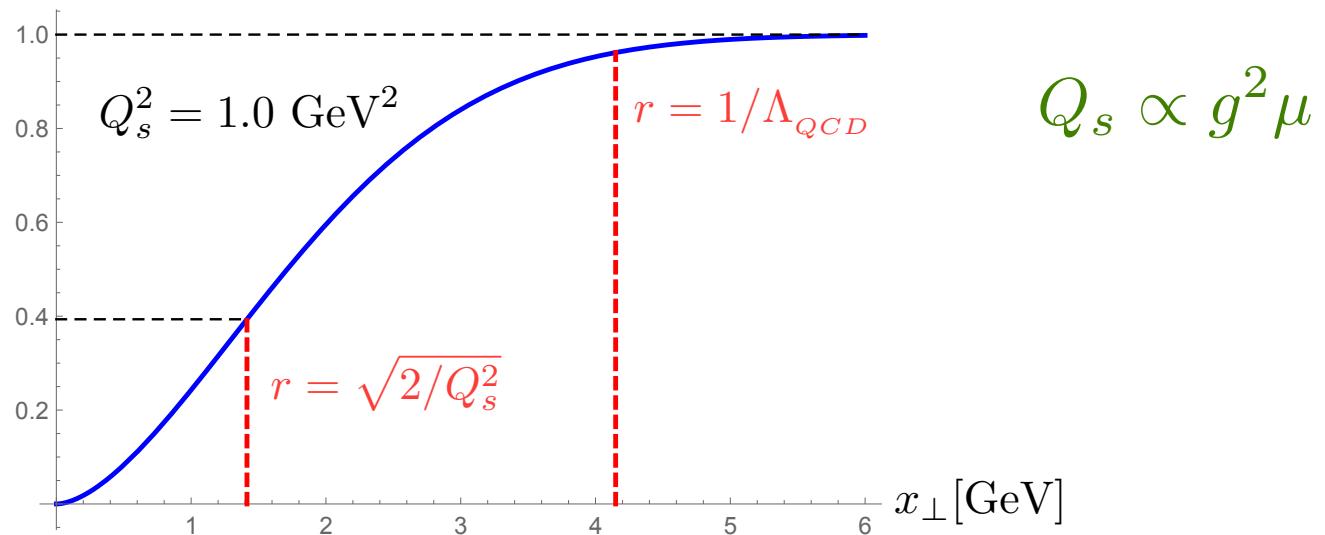

Averaging over color representations in the target

Dipole correlator is evaluated in the MV model where color correlations in the target are Gaussian (random walk in color)

$$g^2 \langle A_a^-(x) A_b^-(y) \rangle = \delta^{ab} L_{xy} \quad L_{xy} = -\frac{g^4 \mu^2}{16\pi} |x-y|^2 \ln \frac{1}{\Lambda |x-y|}$$

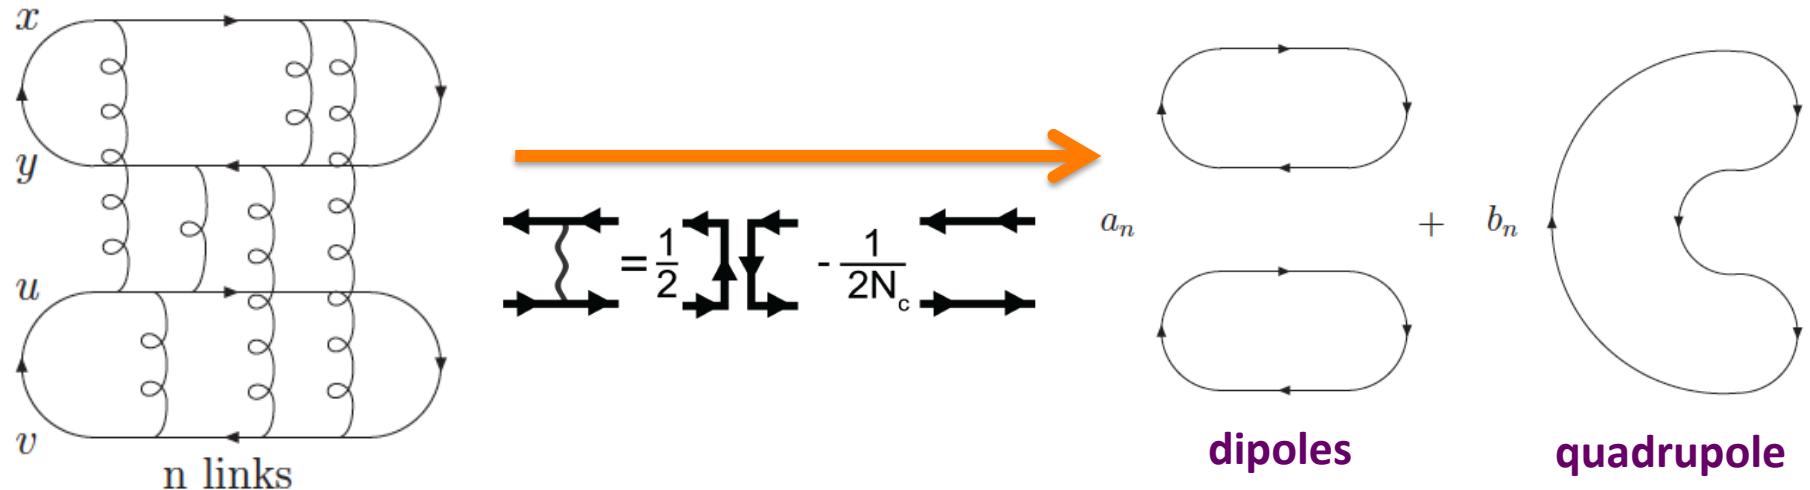

gives $D(x, \bar{x}) = \frac{1}{N_c} \text{Tr} [W(x) W^\dagger(\bar{x})] = \exp(C_F L_{x\bar{x}})$

$$N(x_\perp) = 1 - D(x_\perp)$$

Averaging over multi-point dipole correlators

To compute the 2-dipole correlator:

Use $W(x) \equiv \mathcal{P} \exp \left[ig \int dz^+ A_a^-(z^+, x) \right] \simeq V(x) [1 + igA_a^-(\xi, x)T^a + \dots]$

This gives $\langle D_{x\bar{x}} D_{y\bar{y}} \rangle_W \simeq \alpha_{x\bar{x}y\bar{y}} \langle D_{x\bar{x}} D_{y\bar{y}} \rangle_V + \beta_{xy\bar{x}\bar{y}} \langle Q_{x\bar{y}y\bar{x}} \rangle_V$

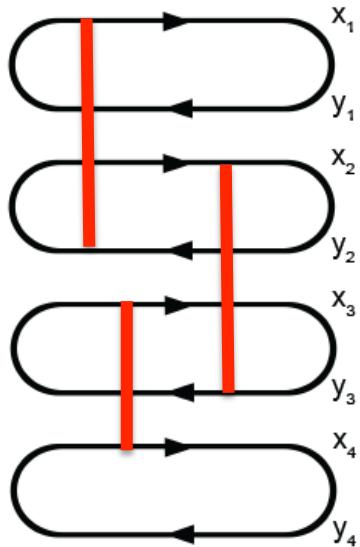

$$\text{Equivalently, } \begin{pmatrix} \langle D_{x\bar{x}} D_{y\bar{y}} \rangle \\ \langle Q_{x\bar{y}y\bar{x}} \rangle \end{pmatrix}_W = \begin{pmatrix} \alpha_{x\bar{x}y\bar{y}} & \beta_{xy\bar{x}\bar{y}} \\ \beta_{xy\bar{y}\bar{x}} & \alpha_{x\bar{y}y\bar{x}} \end{pmatrix} \begin{pmatrix} \langle D_{x\bar{x}} D_{y\bar{y}} \rangle \\ \langle Q_{x\bar{y}y\bar{x}} \rangle \end{pmatrix}_V$$

2m-particle collectivity reproduced in this simple parton model...

Exegesis

Power counting

Three dimensionful scales:

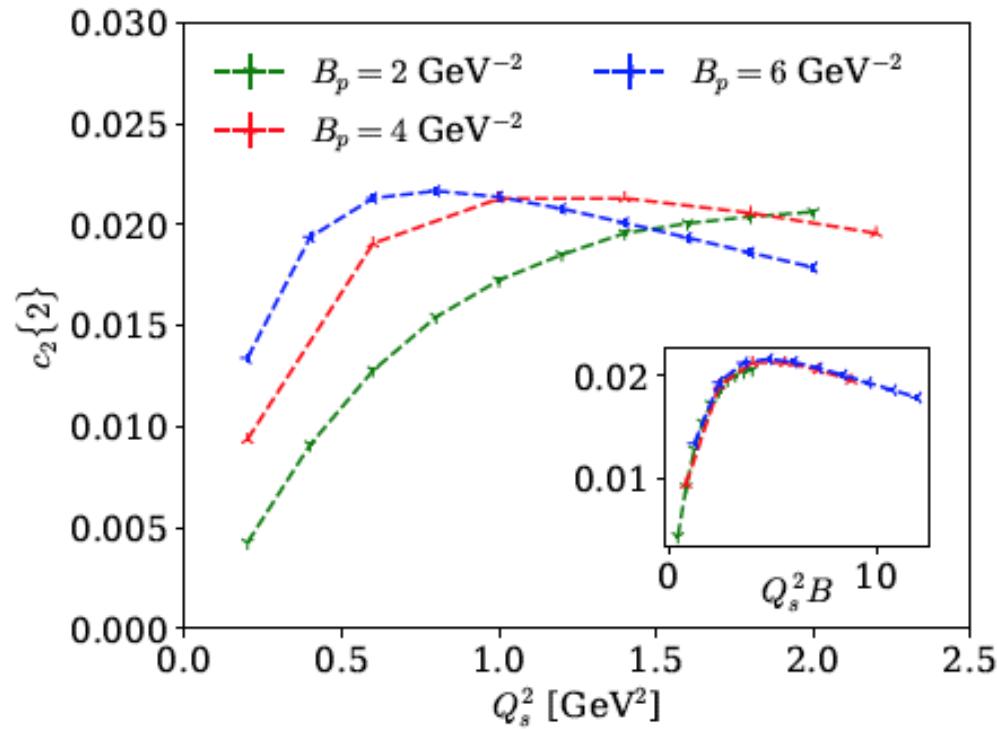

- i) Saturation scale in the target (inverse domain size): Q_s
- ii) Transverse overlap area: B_p
- iii) Maximal momentum kick to projectile: p_T^{\max}

Dimensionless ratios are

of color domains, $Q_s^2 B_p$

Resolving power of projectile, $Q_s^2 / (p_T^{\max})^2$

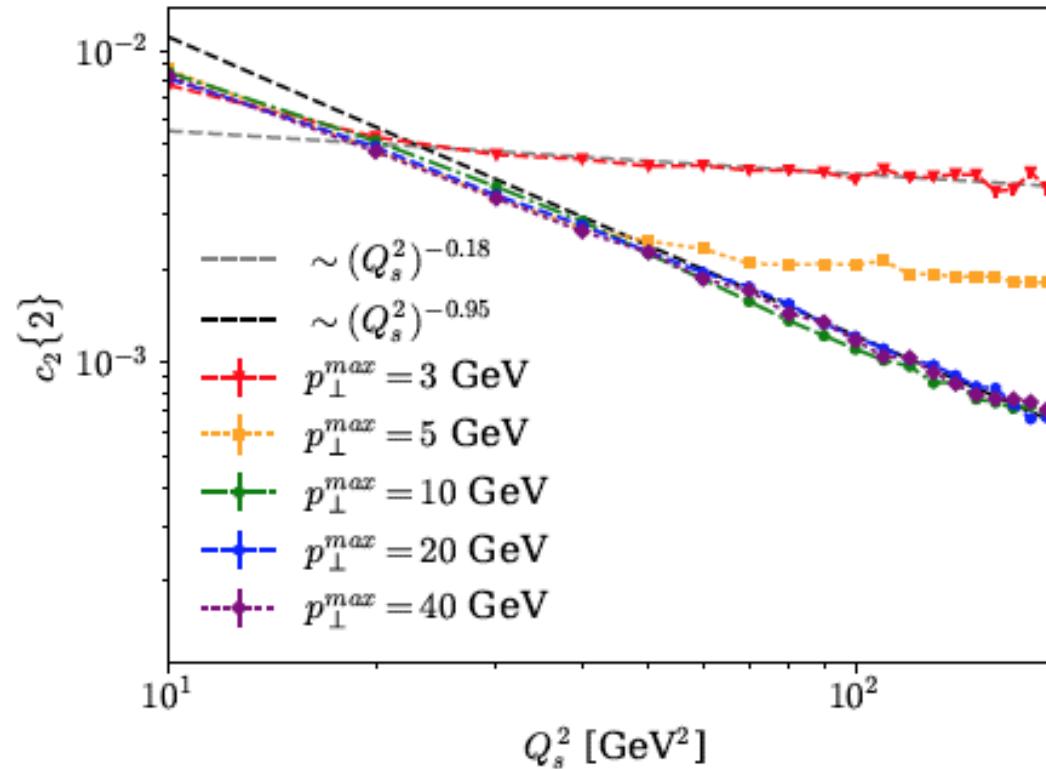

Scaling with # of color domains

“Independent cluster” model: fluctuation driven v_n ’s scale with # of clusters

Basar, Teaney, arXiv:1312.6770

Scaling with # of color domains

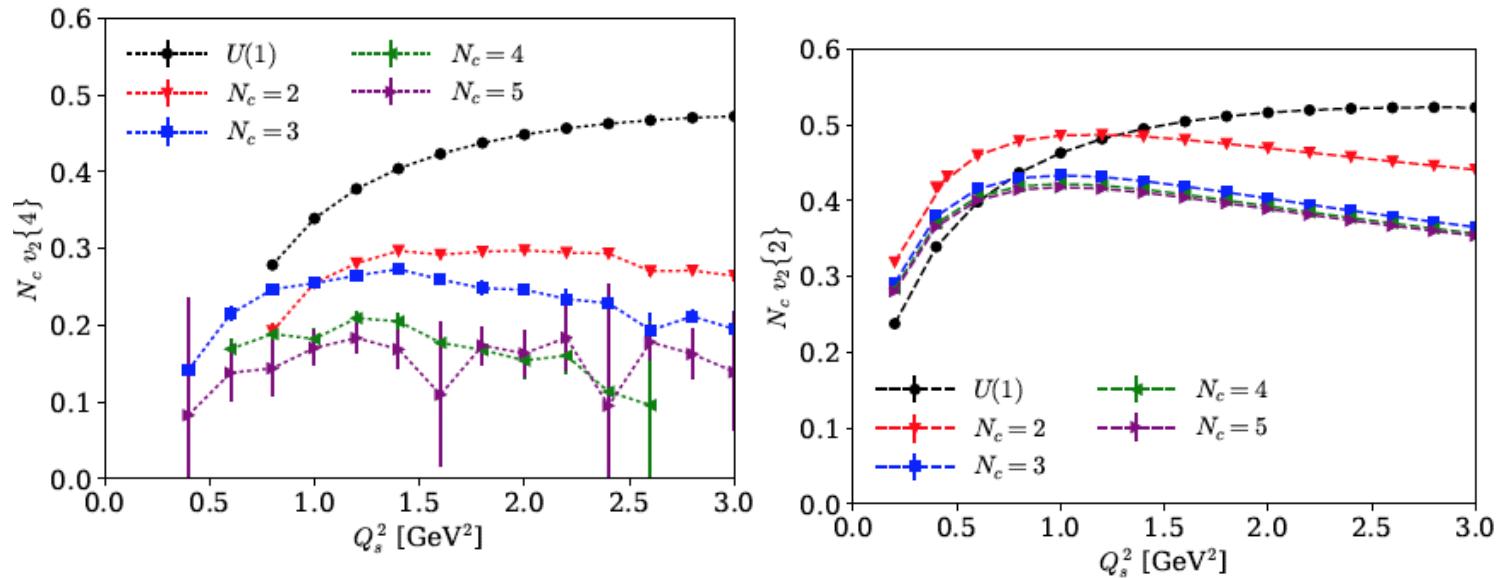

For $(p_T^{max})^2 \gg Q_s^2$, projectile partons resolve individual domains, cumulant scales as $\sim 1/(Q_s^2 B_p)$

For $(p_T^{max})^2 \ll Q_s^2$, partons see fewer domains, weak dependence of cumulant on # of domains.

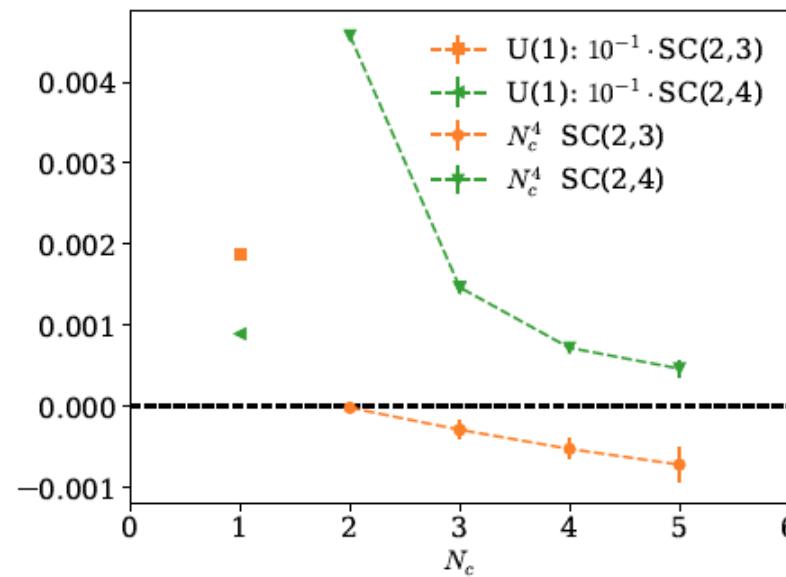

Moral: scaling analyses/conclusions sensitive to p_T window probed in experiments

Scaling with N_c

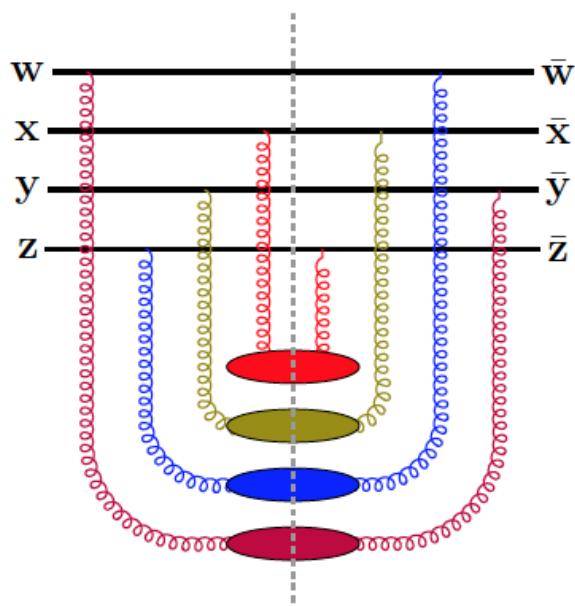

$v_2\{2\}, v_2\{4\}$
scale as $1/N_c$

Symmetric cumulants
show correlations/anti-correlations
seen in experiment only for $N_c \geq 3$

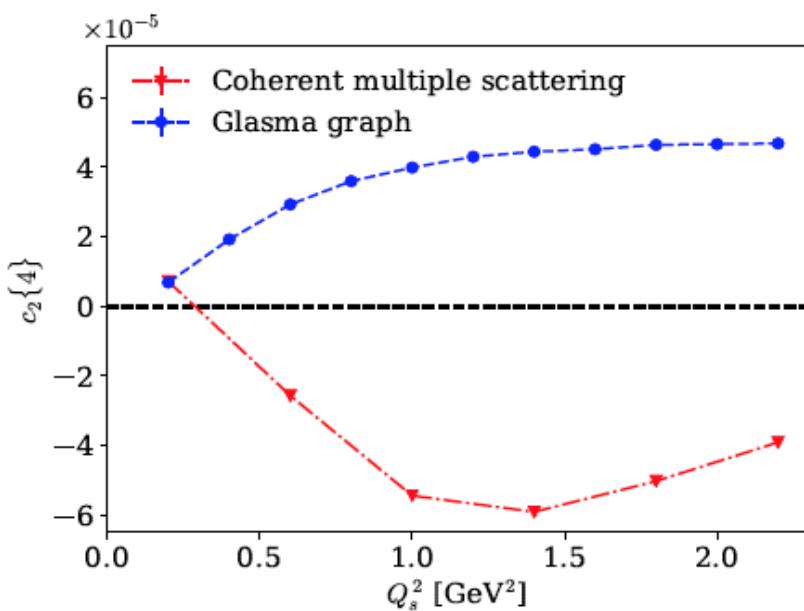

Back to glasma graphs

Glasma graph (single scattering) correlations are very strong – the n-particle distribution is close to a *Bose distribution* – *as in a laser*

Gelis,Lappi,McLerran, arXiv:0905.3234

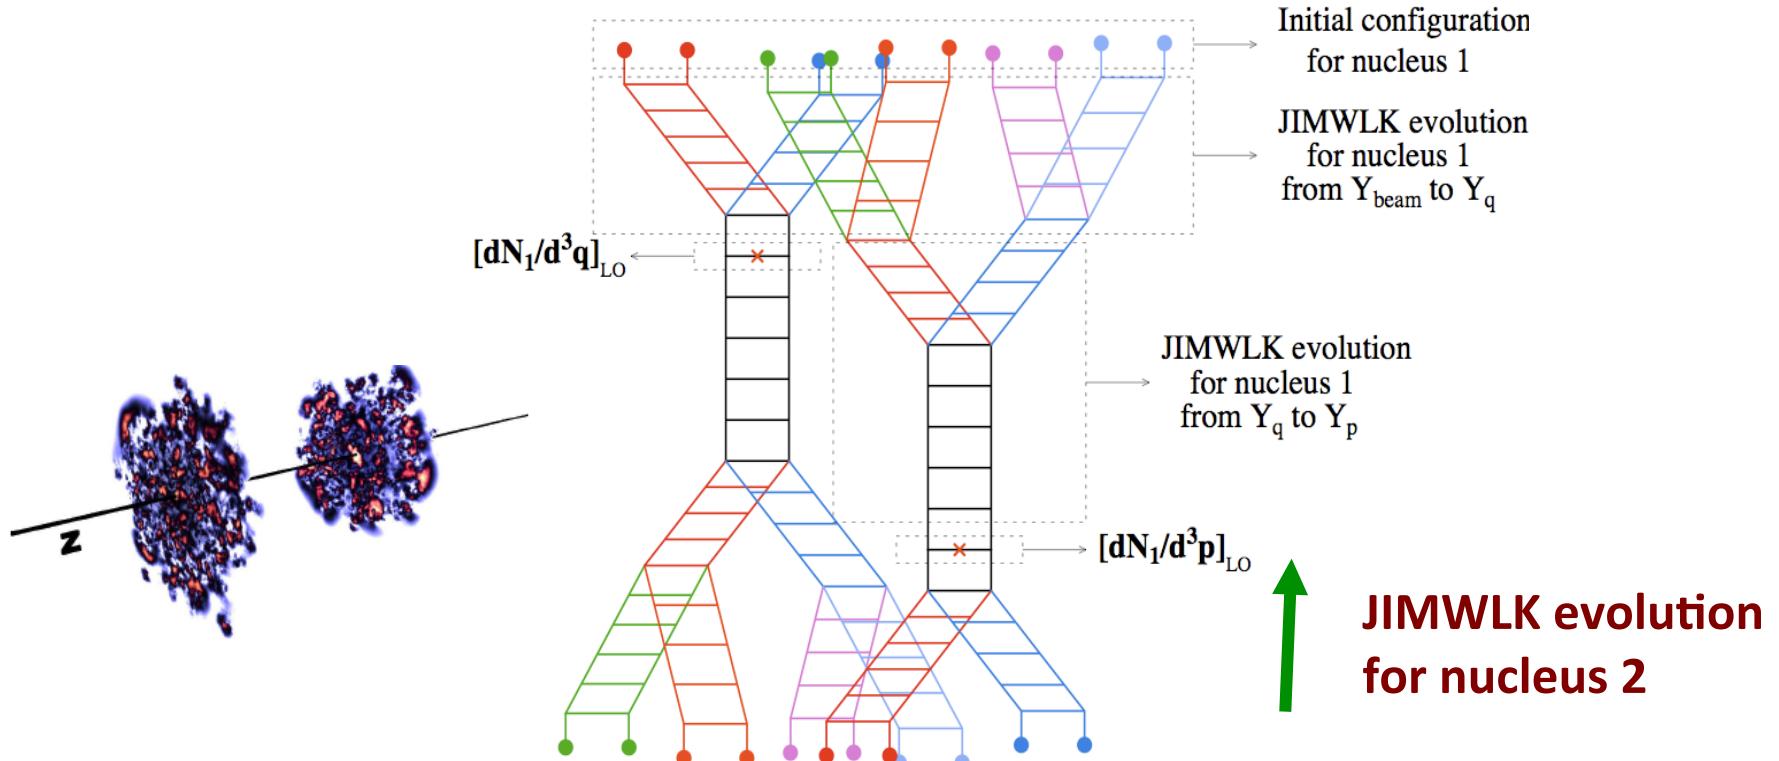

But $v_2\{4\}$ is imaginary...

For real $v_2\{4\}$, must have dominance of first two moments of distribution -- achieved by coherent multiple scattering...

Predictions for p+A symmetric cumulants

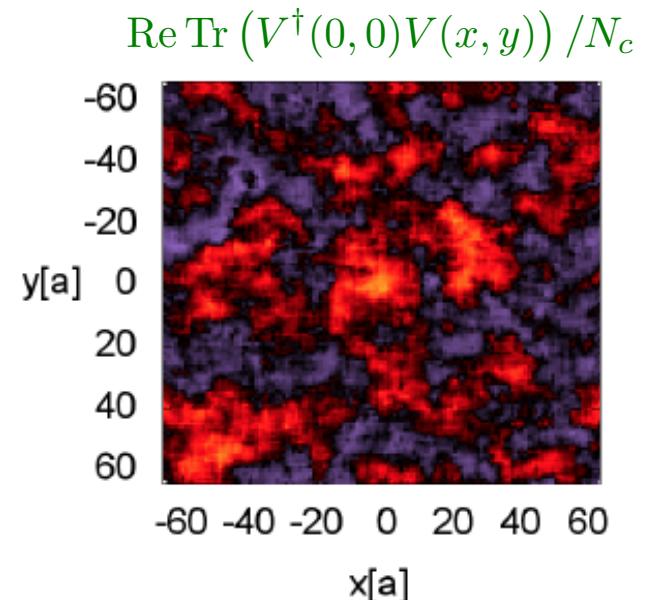

Higher cumulants in the color domain model

Dumitru, McLerran, Skokov, 1410.4844

Color domain model: express intrinsic higher point correlators as correlators of produced particles with a target field in a color domain, averaged over all orientations of the field.

$$c_2\{2\} = \frac{1}{N_D} \left(\mathcal{A}^2 + \frac{1}{4(N_c^2 - 1)} \right) :$$

$$c_2\{4\} = -\frac{1}{N_D^3} \left(\mathcal{A}^4 - \frac{1}{4(N_c^2 - 1)^3} \right)$$

“A” term is the correlation induced between projectile particles due to color field orientation of target (more generically, non-Gaussian correlations)

The N_c term is the “connected Glasma graph” (Gaussian correlations)

N_D is # of color domains – few in p+A, several in A+A
